DEPAREMENT OF THE ARMY Fort Detrick Frederick, Maryland The Status of Race Specialization in Yellow Rust, <u>Puccinia glumarum</u> (Schame) Erikss. et Henn. in Europe.

Von Eva Fuchs, Biologische Bundesanstalt. Institut für Physiologische Botanik, Braunschweig

At the first European Conference on Yellow Rust, the problem of specialization was given much attention. Cambridge, Holland and Braunschweig are prominent in this work.

Allison and Isenbeck (1) and later Wilhelm, Gassner and Straib (5, 6, 7) studied the race flora of Germany on differentials.

Beginning in 1934, Straib (15, 14, 16, 18) continued this work alone. In a search for other methods of differentiation than inoculation and evaluation of differential susceptibility, Straib (14, 16, 17, 18) found differences in individual races in uredospore germination, In reference to germination temperature optimum and the form of germ tubes. On the basis of these observations, he isolated a few races from those already known; e.g., race 40 from 20, 41 from 7, 46 from 45, 47 from 28. The last publication (ref. 18) in the area of yellow rust race specialization describes the discoveries of 1939. At that time, the list consisted of 52.

The files of Braunschweig tests shows that Straib has isolated two other races from the Halle Material, 53 and 54, the infection sictures of which has not published, however.

They are described for the first time in this article. (Table-I).

Race 53 has been mentioned by Becker (2). Noll (10) described an additional race 55 found since 1950. The Braunschweig material contains race 56 isolated from Agrepyron. Manners (9) in 1945-48 found in Cambridge in addition to known races, a new race from Hordeum maritimum. It differs from others by susceptible 0 f on Triticum dicoccum tricoccum, while all others are Type IV.

Manners called it "M". It has been added as Race 57. Race "G" established in the same paper by Manners from Dactylis glomerata was not included in the race list since it has shown "i" on all varieties except Dactylis. This "race" will have to be considered a separate variety.

Table I shows the present complete European race list,

Table II gives historical perspective on yellow rust races defined
to 1954 and a summary on its incidence.

Works outside Europe have not been considered here. They have not been coordinated with the European ones.

Investigation of rusts collected in 1955 has not been concluded. The heretofore customary classification of races requires revision within the next few years. Some of the utilized test varieties have proved labile as regards temperature, light and humidity so that the small differences in susceptible type found in them are not sufficient for differentiation of races. Especially definition

of races on the basis of variable uredospore germination will not be supportable since these are especially dependent upon environment, Straib (17, 18). Some of the races hitherto described probably have only the nature of biotypes in the sense of Chester (3), and Stakman (12) as indicated by Manners (9). The difficulties of a reasonable and exact classification are far greater in yellow rust than in other rusts owing to greater temperature and light lability in host and fungus.

Therefore, Boniture II, e.g., normally gives a medium type susceptible reaction. Under particular conditions, we may be dealing with a scantily erupting type or a 0 f increased to highest potency. Even at controlled conditions, such types as i, 0, or III and IV cannot be strictly differentiated on some varieties.

Table III shows tabulation of races of P. glumarum found on wheat (with the exception of race 13 on H. jubatum), according to its progressive infection on the Gassner and Straib differentials.

In both tables infection types are grouped for convenience,
III and IV to IV; III f and III- to III; T-, II, IIf and II-III to
II; and Of, O-I, O-II, to Of. Both tables are meant as a key to
determination. It need not be explained in more detail that the
practical differentiation depends upon good differentials.

It is difficult to determine the size of a test assortment.

On one hand, it should be as small as possible for reasons of

perspective and technical work; on the other hand, it should permit separation of small differences in order to avoid overlooking blotypes and races.

Since its "founding" the Gassner-Straib assortment has proved essentially feasible so far as it enables the worker to maintain the individual varieties constant in their resistance properties. For this reason and in order not to lose the connection with all previous investigations the Gassner and Straib assortment should be generally accepted as a basic stock and augmentation assortments—possibly different in various contries could be resorted to for extensive differentiation.

The wheat test assortment of Gassner and Straib consists of the following varieties:

- 1. Michigan Amber (completely susceptible control variety)
- 2. Ble rouge d'Ecosse
- 3. Strubes Dickkopf
- 4. Webster
- 5. Holzapfels Frühweizen
- 6. Vilmorin 23
- 7. Heines Kolben
- 8. Carsten V
- 9. Spaldings Prolific
- 10. Chinese 166
- 11. Rouge prolifique barbu

Test variety Triticum dicoccum tricoccum is added which is susceptible to all but race 57.

Some varieties such as Webster, Holzapfels Frühweizen, Heines Kolben, and Carstens V do not entirely meet all test variety requirements so that it must be attempted to reselect pure lines with desired properties.

The European Yellow Rust test centers in conjunction with growers institutes will attack this problem together.

The test assortment for determination of yellow rust races occurring on barley and wild grasses consists of the following barley varieties:

- A. Weisze von Fong Tien (control)
- B. Heils Franken
- C. Estanzuela Futter gerste
- D. Ackermanns Bavaria
- E. Peragis Sommergerste
- F. Schwarze zweizeilige

Straibs work shows show difficult it is to find a barley differential assertment at all. The assertment given here is composed from individual publications and certainly is not final.

In the future the cultivation of test differentials will occur at one location from which the three test centers will be supplied with the necessar, seed every year.

The Max Planck Institute for cultivation research at Koln-Vogelsang has agreed to furnish these.

In order not to overlook any races and to retest some of the races the Netherlands Grain Center has assembled a catch assortment.

This was planted in the fall of 1955 at 58 locations and incorporates

```
the following varieties:
    Winterweizen:
                                     31.
                                          Mentana (I)
    l. Aniversario (III)
                                     32.
                                          Michigan Amber (I)
         Ardennes (IV)
                                     33.
                                          Ministre (III)
    3. Banco (II)
                                     34. Nord (II)
     4. Beauceron (I)
                                     55. Panter (IV)
    5. Believue (II)
                                     36. Prima (IV)

```

### Explanation:

- (I) Very susceptible
- (II) Very susceptible for certain yellow rust races
- (III) Susceptible
- (NY) Somewhat resistant
- (V) Good resistance

In addition to varieties of different susceptibility, varieties of different rate of development have been added in order to determine yellow rust infection at different growth stages.

The cultivation of such a test assortment at many locations possibly coupled with a variable time of seeding has been planned for several years in which connection the composition of the assortment probably will be varied. Only those assortments will be treated which have pathological or cultivative interest. The Netherlands Grain Center will cause a scientist to visit the cultivation points to evaluate the reactions. Since it is impossible to arrive at all locations in time, a large number of the cultivators will have to evaluate the reactions themselves. In order to get uniform results, nevertheless, and considering the fact that heretofore evaluation has been conducted with a variety of schemes in the European area, the first European yellow rust conference has worked out a consistent scheme of evaluation based on the schemes of different authors.

In connection with an exact field evaluation which is also informative for epidemiological questions, three different things should be considered:

- a. Infection type (as in the greenhouse)
- b. Magnitude of infection
- c. State of development of host plants

  The infection types are given in Roman numerals; the magnitude of infection in Arabic numerals (Table V).

The state of growth of host plants should be evaluate cording to Feeke's Scale (4). It has been illustrated by Large (8)
and is depicted here in this form, Figure 1. The three schemes
are also listed in the new edition of "Handbuth der Pflanzenzüchtung"
now in print. (Verlag Paul Parey, Berlin and Hamburg).
